DESCRIPTION

## 5 BACKGROUND OF THE INVENTION

The present invention provides novel compounds. More particularly, the present invention provides novel renin-inhibiting peptide analogs. Most particularly, the present invention provides renin-inhibitory compounds having S-aryl-D- or L- or DL-cysteinyl, 3-(arylothio)lactic acid or 3-(arylothio)alkyl moieties at the 8 position (as compared to the renin substrate described below). The renin inhibitors provided herein are useful for the diagnosis and control of renin-dependent hypertension.

Renin is an endopeptidase which specifically cleaves a particular peptide bond of its substrate (angiotensinogen), of which the N-terminal sequence in equine substrate is for example:

as found by L.T. Skeggs et al, J. Exper. Med. 106, 439 (1957). Human renin substrate has a different sequence as recently discovered by D.A. Tewkesbury et al, Biochem. Biophys. Res. Comm. 99, 1311 (1981). It may be represented as follows:

30

and having the sequence to the left of the arrow ( $\rightarrow$ ) being as designated in formula IA above.

Renin cleaves angiotensinogen to produce angiotensin I, which is converted to the potent pressor angiotensin II. A number of angiotensin I converting enzyme inhibitors are known to be useful in the treatment of hypertension. Inhibitors of renin are also useful in the treatment of hypertension.

INFORMATION DISCLOSURE

A number of renin-inhibitory peptides have been disclosed. Thus, U.S. patent 4,424,207, and European published applications 45,665 and 104,041 disclose certain peptides with the dipeptide at the 10,11-position containing an isostere bond. A number of statine derivatives stated to be renin inhibitors have been disclosed, see, e.g., European published applications 77,028; 81,783; and 114,993; and U.S. patents 4,478,826; 4,470,971 and 4,479,941. Terminal disulfide cycles have also been disclosed in renin inhibiting peptides; see, e.g., U.S. patents 4,477,440 and 4,477,441. Aromatic and aliphatic amino acid residues at the 10,11 position of the renin substrate are disclosed in U.S. patent 4,478,827. C-terminal amide cycles are disclosed in U.S. patent 4,485,099. Certain tetrapeptides are disclosed in European publications 111,266 and 77,027. Further, European published application No. 118,223 discloses certain renin inhibiting peptide analogs where the 10-11 peptide link is replaced by a one to four atom carbon or carbon-nitrogen link. Additionally, Holladay et al., in "Synthesis of Hydroxyethylene and Ketomethylene Dipeptide Isosteres", Tetrahedron Letters, Vol. 24, No. 41, pp. 4401-4404, 1983 disclose various intermediates in a process to prepare stereo-directed "ketomethylene" and "hydroxyethylene" dipeptide isosteric functional groups disclosed in the above noted U.S. Patent No. 4,424,207.

Additionally, published European Applications 45,161 and 53,017 disclose amide derivatives useful as inhibitors of angiotensin converting enzymes.

The present invention provides peptide inhibitors of renin which contain modification of the Phe<sup>8</sup> (angiotensinogen numbering) position. These modifications involve the insertion of a heteroatom-containing fragment into the side chain of the residue occupying the

-11-

Phe<sup>8</sup> position. These changes in the normal Phe side chain result in dramatic changes in the overall length and size of the side chain. The hetero-atom also alters the polarity, angles, and H-bonding ability of the side chain elements. Additionally, changes in the backbone may be made such as substitution of oxygen for nitrogen in the corresponding  $\alpha$ -amino acid. These changes, in addition to being chemically novel to renin inhibitors, also confer stability to the position 8-9 bond to the action of chymotrypsin and elastase due to the lack of fit of the lengthened side chain into the active site pocket of these enzymes.

Examples of pharmaceutically acceptable acid addition salts include: acetate, adipate, alginate, aspartate, benzoate, benzenesulfonate, bisulfate, butyrate, citrate, camphorate, camphorsulfonate, cyclopentanepropionate, digluconate, dodecylsulfate, ethanesulfonate, fumarate, glucoheptanoate, glycerophosphate, hemisulfate, heptanoate, hexanoate, hydrochloride, hydrobromide, hydroiodide, 2-hydroxyethanesulfonate, lactate, maleate, methanesulfonate, 2-naphthalenesulfonate, nicotinate, oxalate, palmoate, pectinate, persulfate, 3-phenylpropionate, picrate, pivalate, propionate, succinate, tartrate, thiocyanate, tosylate, and undecanoate.

The carbon atom content of various hydrocarbon-containing moieties is indicated by a prefix designating the minimum and maximum number of carbon atoms in the moiety, i.e., the prefix (C<sub>1</sub>-C<sub>j</sub>) indicates a moiety of the integer "i" to the integer "j" carbon atoms, inclusive. Thus (C<sub>1</sub>-C<sub>4</sub>)alkyl refers to alkyl of one to 4 carbon atoms, inclusive, or methyl, ethyl, propyl, butyl, and isomeric forms thereof. C<sub>4</sub>-C<sub>7</sub>cyclic amino indicates a monocyclic group containing one nitrogen and 4 to 7 carbon atoms.

25 Examples of pharmaceutically acceptable cations include: pharmacologically acceptable metal cations, ammonium, amine cations, or quaternary ammonium cations. Especially preferred metal cations are those derived from the alkali metals, e.g., lithium, sodium, and potassium, and from the alkaline earth metals, e.g., magnesium and

The novel peptides herein contain both natural and synthetic  
35 amino acid residues. These residues are depicted using standard amino acid abbreviations (see, e.g., Roberts, et al., Basic Principles of Organic Chemistry, pp. 703-705 (New York 1965)) unless otherwise indicated.

All the renin-inhibiting compounds of the present invention may be administered in the conventional forms, such as disclosed in U.S. Patent No. 4,424,207 which is incorporated by reference herein. Likewise, the amounts disclosed in the U.S. Patent No. 4,424,207 are  
5 examples applicable to the compounds of the present invention.

Preferably, the dosages of the present invention are for oral administration for treatment of humans to effect renin inhibition for the purpose of favorably affecting blood pressure. For this purpose, the compounds are administered from 0.1 mg to 1000 mg per kg per  
10 dose, administered from 1 to 4 times daily. Equivalent dosages for other routes of administration are also employed.

The exact dose depends on the age, weight, and condition of the patient and on the frequency and route of administration. Such variations are within the skill of the practitioner or can readily be  
15 determined.

The compounds of the present invention may be pharmaceutically acceptable salts both those which can be produced from the free bases by methods well known in the art and those with which acids have pharmacologically acceptable conjugate bases.

20 The compounds of the present invention are preferably orally administered in the form of pharmacologically acceptable acid addition salts. Preferred pharmacologically acceptable salts for oral administration include the citrate and aspartate salts, although any pharmacologically acceptable salt is useful in this invention,  
25 including those listed above. These salts may be in hydrated form.

The compounds of the present invention are prepared as depicted in the charts and as described more fully in the Preparations and Examples.

The description below refers to the structures depicted on the  
30 formula page and in the Charts A-E. In those formulas, all variables are as defined above except where noted.

Generally, the renin inhibiting polypeptides may be prepared by either polymer assisted or solution phase peptide synthetic procedures analogous to those described hereinafter or to those methods  
35 known in the art. For example, the carboxylic moiety of N<sup>α</sup>-t-butyloxycarbonyl (Boc)-substituted amino acid derivatives having suitable side chain protecting groups, if necessary, may be condensed with the amino functionality of a suitably protected amino acid, peptide or

-14-

polymer-bound peptide using a conventional coupling protocol such as dicyclohexylcarbodiimide (DCC) and 1-hydroxybenzotriazole (HOBT) in methylene chloride or dimethylformamide. The synthetic procedures used to incorporate the novel moieties herein are also described, for example, in U.S. patents 4,424,207; 4,470,971; 4,477,440; 4,477,441; 4,478,826; 4,478,827; 4,479,941; and 4,485,099, and copending application Serial No. 753,198, filed 9 July 1985, all of which are expressly incorporated by reference herein. See, also, published European patent applications 45,161; 45,665; 53,017; 77,028; 77,029; 81,783; 104,041; 111,266; 114,993; and 118,223.

Following coupling reaction completion, the N<sup>α</sup>-Boc moiety may be selectively removed with 45% trifluoroacetic acid/2% anisole (v/v) in methylene chloride. Neutralization of the resultant trifluoroacetate salt may be accomplished with 10% diisopropylethylamine in methylene chloride. In the case of polymer-assisted peptide synthesis, this stepwise, coupling strategy may be partially or completely automated to provide the desired peptide-polymer intermediates. Anhydrous hydrofluoric acid treatment of the peptide-polymer intermediate may then be used to effect simultaneous protecting group removal and cleavage of the peptide from its polymeric support. A notable exception to this includes N<sup>1α</sup>-formyl-indolyl-substituted peptides in which the N<sup>1α</sup>-formyl-indolyl moiety is stable to TFA or HF but may be removed by NH<sub>3</sub> or NaOH. Because FTrp is somewhat unstable to base in synthetic procedures, possibly causing lower yields, it may be desirable in solution phase synthesis to introduce the FTrp-containing moiety late in the synthetic sequence so that it is not exposed to such conditions.

The incorporation of N<sup>1α</sup>-formyl-Trp into compounds of the present invention is easily accomplished because of the commercial availability of N<sup>α</sup>-Boc-N<sup>1α</sup>-formyl-Trp-OH. However, the N<sup>1α</sup>-formyl moiety may be introduced into indolyl-substituted amino acid derivatives or related compounds by reaction with HCl-formic acid as reported in the literature, see A. Previero et al, *Biochim. Biophys. Acta* 147, 453 (1967); Y.C.S. Yang et al, *Int. J. Peptide Protein Res.* 15, 130 (1980).

Generally, methods of alkylation useful in alkylating histidine for use in the present invention are found in Chaung, S.T. et al, *Can. J. Chem.*, Vol 55, pp. 906-910 (1977). However it is now found

-15-

that in Cheung, S. T. et al, methods it is critical that the reaction conditions for the alkylation of histidine be anhydrous. Further, it is now found also that during work-up instead of adding water directly to the reaction mixture, it is preferred that a buffered aqueous solution be added to the reaction mixture, for example, aqueous sodium or potassium hydrogen sulfate.

This is analogous to that found in Cheung, S.T. et al, Can. J. Chem. Vol 55, pp. 906-910 (1977)), however, it has been found that the process requires anhydrous reaction conditions which are not taught by Cheung et al.

Variations in the above description for starting materials, reactants, reaction conditions and required protecting groups to obtain other such N-alkylated compounds are known to an ordinarily skilled chemist or are readily available in the literature.

These peptides may also be prepared by the standard solid phase techniques of Merrifield. Appropriate protecting groups, reagents, and solvents for both the solution and solid phase methods can be found in "The Peptides: Analysis, Synthesis, and Biology," Vols. 1-5, eds. E. Gross and T. Meienhofer, Academic Press, NY, 1979-1983.

The compounds of the present invention may be in either free form or in protected form at one or more of the remaining (not previously protected) peptide, carboxyl, amino, hydroxy, or other reactive groups. The protecting groups may be any of those known in the polypeptide art. Examples of nitrogen and oxygen protection groups are set forth in T.W. Greene, Protecting Groups in Organic Synthesis, Wiley, New York, (1981); J.F.W. McOmie, ed. Protective Groups in Organic Chemistry, Plenum Press (1973); and J. Fuhrhop and G. Benzlin, Organic Synthesis, Verlag Chemie (1983). Included among the nitrogen protective groups are t-butoxycarbonyl (Boc), benzyloxycarbonyl, acetyl, allyl, phthalyl, benzyl, benzoyl, trityl and the like.

In general, the processes of the present invention may be carried out in the following manner.

The synthesis of the key intermediate, Boc-(R,S)-3-(phenylthio)alanine, is shown in Chart A. This synthesis follows the method of G. Glynn and D. Beight, Tet. Lett.; 25:2655 (1984). Boc-Serine (Boc-D,L-Ser may be used as chirality is lost at a later step) is

-16-

converted to its methyl ester using a five-fold excess of methyl iodide and two equivalents of  $\text{NaHCO}_3$  in DMF as solvent. The alcohol (A-2) is then converted to the mesylate with methanesulfonyl chloride and 1 equiv. of  $\text{Et}_3\text{N}$  in  $\text{CH}_2\text{Cl}_2$ . Addition of a second equivalent of  $\text{Et}_3\text{N}$  gives the elimination product A-3. Compound A-3 is stirred with 1.1 equivalents of thiophenol and a catalytic amount of  $\text{Et}_3\text{N}$  in MeOH to give A-4. Hydrolysis of the methyl ester with aq. NaOH in MeOH, followed by acidification, gives Boc-(R,S)-3-(phenylthio)alanine A-5.

The peptides are synthesized by methods known to the art. See, for instance, the series "The Peptides: Analysis, Synthesis, Biology, Vols. 1-5, eds. E. Gross and J. Meienhofer, Academic Press, New York, 1979-1983. The assembly of Boc-(R,S)-3-(phenylthio)alanyl-His-LeuY[CH(OH)CH<sub>2</sub>]Val-Ile-2-(amidomethyl)pyridine is shown in Chart B. Boc-Ile and 2-(aminomethyl)pyridine (both commercially available) are coupled using DCC in  $\text{CH}_2\text{Cl}_2$  and aq.  $\text{NaHCO}_3$  to give B-3. Boc-LeuY[CH(OTBDMS)-CH<sub>2</sub>]Val-OH is coupled to Ile-AMP (AMP-2-(amidomethyl)pyridine) using DEPC (diethyl cyanophosphonate) and  $\text{Et}_3\text{N}$  in  $\text{CH}_2\text{Cl}_2$  to give B-4. The Boc group of B-4 is removed with TFA and  $\text{CH}_2\text{Cl}_2$  and the resulting TFA salt is neutralized by extraction with  $\text{CH}_2\text{Cl}_2$  and aq.  $\text{NaHCO}_3$ . LeuY[CH(OTBDMS)-CH<sub>2</sub>]Val-Ile-AMP is coupled with Boc-His(Tos)-OH using DEPC and  $\text{Et}_3\text{N}$  in  $\text{CH}_2\text{Cl}_2$  to give B-5. The Boc group and tert-butyldimethylsilyl group of B-7 are removed with TFA and  $\text{CH}_2\text{Cl}_2$ . The resulting TFA salt is neutralized via extraction with  $\text{CH}_2\text{Cl}_2$  and aq.  $\text{NaHCO}_3$  to give B-6. Compound B-6 is coupled with Boc-(R,S)-3-(phenylthio)alanine using DCC in  $\text{CH}_2\text{Cl}_2$ . The tosyl protecting group on the histidine side chain is removed with 1-HOBT and MeOH to give the final product, B-7. In a similar manner, the mercaptide anion of cycloalkyl-SH or alkyl-SH (formed from , for instance, the commercially available mercaptan and NaOMe or NaH) is added to A-3 and carried through the sequences of Charts A and B to give compounds such as A-5 and B-7 in which cycloalkyl-S- and alkyl-S-replace aryl-S-.

The syntheses of key intermediates C-4A and C-5 are shown in Chart C. Commercial L-malic acid is converted to the halide C-2 via the method of Larcheveque and Petit, Tet. Letters, 25:3705 (1984) and references cited therein. Reaction of C-2 with thiophenoxide anion (generated from thiophenol and base) gives ester C-3. Ester C-3 is hydrolyzed with aqueous NaOH in MeOH, followed by acidification, to

-17-

give acid C-3A. Acid C-3A is converted to the O-acetate with  $\text{Ac}_2\text{O}$  in pyridine to give C-4A. Coupling of C-3A with  $\text{His}(\text{Tos})\text{-Leu}\Psi\text{-}[\text{CH}(\text{OH})\text{CH}_2]\text{Val-Ile-AMP}$  using DEPC and  $\text{Et}_3\text{N}$  in  $\text{CH}_2\text{Cl}_2$ , followed by removal of the tosyl group with 1-HOBT, gives C-5A. Compound C-3 is converted to the carbamate derivate C-4 with diethyl carbamoyl chloride,  $\text{NaH}$ ,  $\text{Et}_3\text{N}$ , and THF. Compound C-4 is hydrolyzed to the acid with aqueous  $\text{NaOH}$  in  $\text{MeOH}$ , followed by acidification. Coupling of C-5 with  $\text{His}(\text{Tos})\text{-Leu}\Psi\text{-}[\text{CH}(\text{OH})\text{CH}_2]\text{Val-Ile-AMP}$  using DEPC and  $\text{Et}_3\text{N}$  in  $\text{CH}_2\text{Cl}_2$ , followed by removal of the tosyl group with 1-HOBT in  $\text{MeOH}$ , gives C-6. In a similar manner, the mercaptide anions, cycloalkyl- $\text{S}^-$  and alkyl- $\text{S}^-$  (from the mercaptan and a base such as  $\text{NaOMe}$  and  $\text{NaH}$ ), may be added to C-2 and carried through the above sequence to give compounds of the general structures C-5A and C-6 with cycloalkyl- $\text{S}^-$  and alkyl- $\text{S}^-$  replacing aryl- $\text{S}^-$ .

The synthesis of D-5 is outlined in Chart D. Reaction of thiophenoxide anion with ethyl acrylate gives ester D-2. Hydrolysis of D-2 with aqueous  $\text{NaOH}$  and  $\text{MeOH}$ , followed by acidification, gives acid D-3. Coupling of D-3 with  $\text{His}(\text{Tos})\text{-Leu}\Psi\text{-}[\text{CH}(\text{OH})\text{CH}_2]\text{Val-Ile-AMP}$  using DEPC and  $\text{Et}_3\text{N}$  in  $\text{CH}_2\text{Cl}_2$ , followed by removal of the tosyl group with 1-HOBT in  $\text{MeOH}$ , gives D-5.

Chart E outlines the synthesis of intermediates for the preparation of compounds of this invention wherein X is  $\text{R}_6\text{-(CH}_2)_1\text{-C(=O)-}$  from known (commercially available) halo ester E-1 or halo ester E-3. Halo ester E-1 is reacted with the mercaptide anion of  $\text{R}_6\text{SH}$  to give thio ether E-2, which is hydrolyzed to give acid E-5. Alternatively halo acid E-3 is converted to a salt such as the sodium salt E-4 which is reacted with the anion of  $\text{R}_6\text{SH}$  followed by acidification to give acid E-5. In the same manner as the conversion of D-3 to D-5, E-5 may be incorporated into peptides of this invention, e.g., D-5.

Example 2 3-(Phenylthio)propionyl-His-Leu $\Psi$ [CH(OH)CH<sub>2</sub>]Val-Ile-AMP

A mixture of 0.0139 g (0.0763 mmoles) of 3-(phenylthio)propionic acid, 0.0503 g (0.0694 mmoles) of His(Tos)-Leu $\Psi$ [CH(OH)CH<sub>2</sub>]Val-Ile-AMP, 0.0126 ml (0.0832 mmoles) of DEPC, 0.0116 ml (0.0832 mmoles) of  $\text{Et}_3\text{N}$ , and 3 ml of  $\text{CH}_2\text{Cl}_2$  is stirred at room temperature for 2 hours. The reaction is extracted with  $\text{CHCl}_3$  and aq.  $\text{NaHCO}_3$  and the organic layers are filtered through  $\text{Na}_2\text{SO}_4$  and concentrated.  $\text{CH}_2\text{Cl}_2$  and hexane are added to the residue and, after cooling in the refrigerator, the solvent is decanted. The remaining solid is stirred for 40 hours with 0.031 g of 1-HOBT in 30 ml of MeOH and 5 ml of  $\text{CH}_2\text{Cl}_2$ . The solvents are then removed in vacuo and extraction with  $\text{CHCl}_3$ -aq.- $\text{NaHCO}_3$  is attempted. This results in a bad precipitation of product (mostly suspended in the aqueous phase). The  $\text{CHCl}_3$  layer is removed and the aqueous suspension is centrifuged and decanted. The pellet is centrifuged twice with  $\text{H}_2\text{O}$  and the remaining solid is absorbed onto silica gel and chromatographed on silica gel (10 g) using 8% MeOH- $\text{CH}_2\text{Cl}_2$  ( $\text{NH}_4\text{OH}$  sat'd) to give 0.0352 g of the titled compound.
